TOPIC TAGS: ~~atmospheric phenomena~~, atmospheric temperature, atmospheric precipitation, meteorologic observation, *climatic condition*

ABSTRACT: Current problems concerning the selection of duration of an averaging period in meteorological observations have been investigated. A new experimental method of checking the degree of climatic stabilities, based on a number of atmospheric temperature and precipitation observations has been suggested. The authors present tabulated data on average differences between mean temperatures

TITLE: Effect of the Caspian Sea on coastal temperature conditions from data accumulated by the Gasan-Kuli weather station

SOURCE: Leningrad. Glavnaya geofizicheskaya observatoriya. Trudy, no. 181, 1965.  
Voprosy obshchey i sinopticheskoy klimatologii (Problems in general and synoptic climatology), 114-120

TOPIC TAGS: climatology, weather station, atmospheric temperature

ABSTRACT: The records of the Gasan-Kuli weather station are analyzed to determine the effect of a large body of water (the Caspian Sea) on air temperature. The changes in thermal conditions on the eastern coast of the sea are quantitatively determined as a function of the drop in sea level. There has been a reduction in sea level from 291 cm in 1927 to 183 cm in 1958 which has exposed a considerable portion of the bottom. This change has affected both the average air temperature and the amplitude of the yearly variation in air temperature. It is shown that the minimum average yearly temperature has decreased by nearly two degrees. The exposure of the sea bottom has also had a considerable effect on the average monthly air temperature, the maximum air tempera-

A study of the results of rain-gauge and precipitation-gauge observations (Issledovaniye rezul'tatov nablyudeniya po dozhdemeru i osadkomeru) Leningrad, Gidrometeoizdat, 1965. 169 p., illus., biblio., append. Errata slip inserted. 900 copies printed. (At head of title: Glavnoye upravleniye gidrometeorologicheskoy sluzhby pri Sovete Ministrov SSSR. Glavnaya geofizicheskaya observatoriya im. A. I. Voyeykova). Editor: L. I. Shtannikova; Technical editor: G. V. Ivkova; Proofreaders: Z. A. Belkina, K. I. Rozinova

TOPIC TAGS: atmospheric precipitation, Nipher shield, precipitation gauge, rain gauge, snow gauge, Tretyakov shield

PURPOSE AND COVERAGE: This book was intended for a wide circle of specialists, including meteorologists and hydrologists, working on both practical and design problems. Problems connected with replacing a rain gauge having a Nipher shield with a precipitation gauge having a planar shield of the Tretyakov system are discussed. Conversion factors are derived for solid precipitates at meteorological stations, depending on the wind velocity and the type of shielding installation on the instrument, by special

TITLE: On the problem of relating the amount and number of days with solid, liquid, and mixed precipitation on per monthly basis

SOURCE: Leningrad. Glavnaya geofizicheskaya observatoriya. Trudy, no. 195, 1966. Voprosy metodiki izmereniya atmosferykh osadkov (Problems in methods of measuring atmospheric precipitation), 81-87

TOPIC TAGS: weather forecasting, atmospheric precipitation, measurement error

ABSTRACT: In order to determine the real amount of precipitation and account for the errors introduced when the different types of precipitation are combines, the author attempts to find the percentage of precipitation of each type on per monthly basis for the European portion of the Soviet Union. The precipitation data from 19 meteorological stations collected during the period from 1936 to 1955 is used for computer analysis. The results are listed in the table giving the percent of solid, liquid, and mixed precipitation during each month for each of the 19 stations. The results show that solid precipitation amounts to 10--30% of the total yearly precipitation. The percentage of liquid precipitation by quantity is greater than that obtained by totaling the number of days per year when the liquid precipitation was observed.

Card 1/2

ACC NR: AT6036741

This relationship is inverse for the solid precipitation. Formulas are given for relating the amount of solid precipitation to the air temperature and the geographical distribution of the given types of precipitation during the transitory months. These formulas, however, are not very accurate. Orig. art. has: 2 formulas and 3 tables.

On Some Peculiarities of Rotating He II.  
Zhurn. eksp. i teor. fis., 31, fasc. 5, 912-912 (1956)  
Issued: 1 / 1957

At first several previous works dealing with this topic are cited. An experimental confirmation of the dependence of the inertia moment of rotating He II on velocity and an estimation of relaxation time would be most desirable. This problem could be solved by studying the damping of the rotation of a glass with He II which is the nearest approach to the continuous equilibrium between the normal and the superconductive component. As relaxation time was not known, the rotating system had to have sufficiently low damping. For this purpose a plexiglass vessel was suspended in a magnetic field which warranted rotation of the vessel for several hours after an initial velocity of several revolutions per second had been imparted to it. The vessel ( $R = 1,5$  cm) contained about 300 light aluminium disks which were arranged at a shorter distance than the depth of penetration of the viscous wave. With the help of a rotating magnetic field the rotation velocity of the vessel containing the He II was brought up to the assumed value, after which the field was switched off. Under these conditions only the normal component of the He II could at first be taken away with the disks, but with its supraliquid component this was possible only after relaxation time. If relaxation time exceeds the time of screwing-out (?), it was obvious that, with a growing distance of the supraliquid component, a consider-

TITLE: On the Film Flow Rate in Solutions of Helium-Isotopes  
(O skorosti perenosa po plenke u rastvorov geliya)

PERIODICAL: Zhurnal Eksperimental'noy i Teoreticheskoy Fiziki, 1958,  
Vol. 34, Nr 1, pp. 233-234 (USSR)

ABSTRACT: The influence of  $\text{He}^3$  dissolved in He II upon the film flow is, as is well-known, reduced to the decrease in the flow rate. It was of a certain interest to investigate this fact more thoroughly and therefore the authors made tests with a solution of helium-isotopes with a helium content of 1,5; 4,7; 7,0 and 9,6 %. The apparatus used for these tests consists of two elbows of a thin-walled capillary tube (diameter 1,08 mm) of equal lengths communicating over a helium-film. The film flow rate  $R = v\delta$  was measured by the measurement of the rate of change of the liquid level in one of these elbows. In this connection  $v$  signifies the rate of the motion of the film and  $\delta$  - the thickness of the film. The temperature interval immediately following the  $\lambda$ -point was investigated. The results obtained here are illustrated in two diagrams. One of these diagrams

Card 1/3

On the Film Flow Rate in Solutions of Helium-Isotopes

56-1-38/56

illustrates the dependence of the film flow rate on the temperature and the other diagram - the dependence of the film flow rate on the content of  $\text{He}^3$ . According to the results found here the film flow rate increases with increasing concentration of  $\text{He}^3$ . When having data on the dependence of the density on the temperature for the solutions of the helium-isotopes, the following conclusions can be drawn: The film flow rate in the temperature range investigated here is directly proportional to the density of the superliquid component:  $R = A \rho_s / \eta$ , where  $A = 3,2 \cdot 10^{-5} \text{ cm}^3 / \text{cmsec}$ . Moreover the temperature of the phase transition He I - He II for the solutions given here might be determined from the beginning of overflowing over the film. The values obtained in this connection are in satisfactory agreement with the analogous results obtained by other methods. There are 2 figures, 2 tables, and 5 references, 4 of which are Slavic.

TITLE:

The Use of a Superconductive Ring for Recording the Phase Transition in Liquid Helium (Ispol'zovaniye sverkhprovodyashchego kol'tsa dlya registratsii fazovogo perekhoda v zhidkom gelii)

PERIODICAL:

Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1959, Vol 37, Nr 1, pp 323 - 324 (USSR)

ABSTRACT:

For the purpose of investigating the properties of  $\text{He}^3$ -solutions in  $\text{He}^4$ , and especially for the purpose of investigating the properties of rotating helium, a ring made from a superconductor may be used (A. A. Gal'perin, Ya. S. Kan and B. G. Lazarev worked with a lead ring for the purpose of investigating the transition into the superconductive state and measuring the thermal conductivity of copper). The ring is especially well suited for recording phase transitions if its current-conduction properties are known. The authors of the present "Letter to the Editor" describe experiments carried out with a lead ring in a plexiglass container with liquid helium at  $1.5^\circ\text{K}$  in the case of a slow transition from He II to He I. The experi-

Card 1/2

The Use of a Superconductive Ring for Recording the Phase Transition in Liquid Helium

SCV/56-37-1-61/64

mental results are shown by a diagram. It shows the deviation  $\alpha$  of the mirror galvanometer connected to the immobile coil in dependence on the time  $t$  (during which helium temperature increases). The curve  $\alpha(t)$  has a slight  $\alpha$ -decrease with an increase of helium temperature from 1.5°K to the  $\lambda$ -point (from  $t=0$  to  $t=17.5$  min), after which there is a sharp increase (to about 30 times its amount) in the  $\lambda$ -point, corresponding to the jump of thermal conductivity at this point. This narrow and steep peak is followed by a second small maximum; At  $T = 3.73^\circ\text{K}$  and  $t = 36.5$  min,  $\alpha$  decreases to zero. In these experiments helium was heated by light; in the case of electrical heating, the peak in the  $\lambda$ -point of the  $\alpha(t)$ -curve does not exist. The authors finally thank Professor B. G. Lazarev for discussing the results. There are 1 figure and 2 Soviet references.

TITLE: An He<sup>3</sup> apparatus for the production of temperatures down to 0.3 °K

PERIODICAL Priroda i tekhnika eksperimenta no.6, 1963, 123-124

TEXT: The apparatus is illustrated in the figure. About 2 litres of gaseous He<sup>3</sup> supplied by the cylinders 1 are condensed into the copper container 2 which is located inside the vacuum envelope 3 and is maintained at the temperature of the outer bath (2.3 °K). Since at this temperature the vapour pressure of He<sup>3</sup> is greater than the pressure at which diffusion pumps begin to operate, there is an additional He<sup>4</sup> bath 4 whose temperature may be reduced to 1 °K by pumping the vapour through a diaphragm by the DRN-50 (DRN-50) pump 5. The valve 6 is used to fill this bath with liquid He<sup>4</sup> from a dewar. Under these conditions the vapour given off by liquid He<sup>3</sup> may be pumped by the mercury diffusion pump (Leybold) 7 which has a pumping speed of about 15 litres/sec. Mercury vapour is excluded by liquid nitrogen traps. The He<sup>3</sup> vapour pumped by 7 is

An  $\text{He}^3$  apparatus for the production of

continuously removed by the liquid-hydrogen cooled charcoal pump 8 containing about 50g of activated charcoal. In this way the  $\text{He}^3$  gas can be recovered and returned into the reservoirs 1. The use of these absorption pumps greatly simplifies the design of cryostats containing  $\text{He}^3$ . It was found convenient to use a solution of  $\text{He}^3$  in  $\text{He}^4$  instead of pure  $\text{He}^4$  as the cooling medium. To do this, a mixture containing 7.4% of  $\text{He}^3$  was condensed through the tube 9 into the glass reservoir 10 which was sealed into the  $\text{He}^3$  container through a Kovar seal. Since this cryostat was used to study the properties of  $\text{He}^3$  -  $\text{He}^4$  mixtures, the reservoir 10 contained the glass vessel 11 which was filled with the mixture under investigation through the tube 12. It was found that the minimum temperature was 0.4°K and could be maintained for about 6 hours, which is much longer than the period obtained with  $\text{He}^4$  as the cooling liquid. The lower temperature of 0.3°K was obtained by pumping the vapour given off by liquid  $\text{He}^4$  placed in a very small glass dewar connected to the pumping system described above. The latter temperature could be maintained for over 7 hours. Temperatures below

An He<sup>3</sup> apparatus for the production

1 and 0.4 °K. could be obtained by adjusting the pumping speed of the diffusion pump with the aid of the valve 13. In all the experiments the temperature was determined by measuring the He<sup>3</sup> vapour pressure with a McLeod gauge (Ref. 14 S. G. Sydorik, T.R. Roberts, Phys. Rev., v. 106, 1957, 175). In one of the experiments the He<sup>3</sup> vapour was pumped by the absorption pump only the pump being cooled by liquid helium (4.2 °K). In spite of the long and narrow connecting pipe, a temperature of 0.4 °K was obtained. This indicates that He<sup>3</sup> cryostats can be considerably simplified by using absorption pumps only. TITLE: A magnetic suspension for investigations at low temperatures

PERIODICAL: Priory i tekhnika eksperimenta, no.6, 1961, 144-148

TEXT: An arrangement is described in which the apparatus is suspended by a magnetic field and is capable of being used at low temperatures. In this particular case, it is used in an experiment to determine the moment of inertia of rotating liquid helium II. [Abstractor's note: The experimental results are not given.] The apparatus to be suspended is attached to a ferromagnetic cylinder which is supported by the field of an electromagnet. When the cylinder moves from its equilibrium position, the magnetic field is automatically changed in such a way as to return the cylinder to its original position. The control of the electromagnet is accomplished by means of an inductive coil which surrounds the ferromagnetic cylinder. This coil is included in the grid circuit of an oscillator in an electronic control unit and the electromagnet is included in the anode circuit of its output valve. The changes in amplitude of the

oscillations generated, which depend on the distance between the ferromagnetic cylinder and the centre of the controlling coil, produce the required change in current through the electromagnet. The liquid helium apparatus is briefly described and consists essentially of a plexiglass bucket, which contains the liquid helium, attached to the ferromagnetic cylinder by means of a duralumin tube. The whole of this suspended system can be brought into rotation by an external rotating magnetic field. The number of revolutions of the suspended system is also counted electronically. The signal to the electronic counting unit is obtained from a condenser, which consists of two brass plates (10 x 5 mm) placed one on each side of the system just below the control coil. Another metal plate attached to the suspended system rotates between these plates, producing two changes in capacity for each revolution. Acknowledgments are expressed to K.D.Sidel'nikov for advice. TITLE: A simple He<sup>3</sup> cryostat

PERIODICAL: Priory i tekhnika eksperimenta, no.3, 1962, 198-199

TEXT: It is pointed out that existing He<sup>3</sup> cryostats capable of producing temperatures down to 0.3 °K are rather complicated because they incorporate diffusion pumps and/or rotary pumps to pump the vapour above liquid helium and thereby reduce the temperature. The present authors have used a charcoal adsorption pump to remove the vapour and thereby have simplified the construction and succeeded in producing temperatures down to

0.34 °K. The device is shown in the figure, in which:

1 - charcoal pump; 2 - thin-walled stainless steel tube; 3 - reservoir containing He<sup>3</sup>; 4, 10 - cylinders for storing helium gas; 5 - vacuum jacket; 6 - valve connecting the charcoal pump 1 to the reservoir 3; 7 - dewar with liquid helium at 1.3 °K; 8 - container filled either with He<sup>3</sup> - He<sup>4</sup> solution (7.4% He<sup>3</sup>) or pure He<sup>4</sup>; 9 - not given; 11 - tube for removing helium gas.

TITLE: Temperature dependence of the electrical resistivity of iron  
in the region of 0.38 to 4.2 °K  
PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 42,  
no. 6, 1962, 1488 - 1489

TEXT: Temperatures were produced by pumping out He<sup>3</sup> vapor from the  
experimental apparatus by means of a carbon absorption pump. For a  
measuring current of 150 ma and with compensated earth field, the residual  
electrical resistance of the very pure iron specimen is given by  
 $R(0^{\circ}\text{K})/R(0^{\circ}\text{C}) = 3.9606 \cdot 10^{-3}$ ;  $R(0^{\circ}\text{K}) = 1.2595 \cdot 10^{-3}$  ohm. The voltages were  
measured to an accuracy of  $10^{-8}$  volt by using a compensation circuit. The  
temperature was ascertained to an accuracy of  $10^{-2}$  °K from the helium  
pressure. The temperature dependence of the resistance can be represented  
by  $R = 3.9606 \cdot 10^{-3} + 3.1 \cdot 10^{-6}T + 1.1 \cdot 10^{-6}T^2$ . The linear term in  $R(T)$  is

TITLE: The surface tension of  $\text{He}^3$ - $\text{He}^4$  solutions  
PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 44,  
no. 2, 1963, 483-486

TEXT: The authors continue previous investigations (DAN SSSR, 99, 365, 1954) where they had measured the surface tension in an  $\text{He}^3$ - $\text{He}^4$  mixture up to 3%  $\text{He}^3$ ; now they measured it up to 75%  $\text{He}^3$ . The experimental apparatus was the same as before, only some variations in size having been made. A temperature regulator kept the temperature constant with an accuracy of  $5 \cdot 10^{-6} \text{ }^\circ\text{K}$ . The surface tension  $\alpha$  was calculated with the relation  $2\alpha(1/b_1 - 1/b_2) = (\rho_l - \rho_v)gh$ , where  $b_1$  and  $b_2$  are the radii of curvature of the lowest points of the menisci of the two capillaries ( $r_1 = 2.69 \text{ mm}$ ,  $r_2 = 0.12-0.22 \text{ mm}$ ),  $\rho_l$  and  $\rho_v$  are the liquid vapor densities,  $g$  the gravity constant and  $h$  the distance between the lowest  
Card 1/2

The surface tension of ...

S/056/63/044/002/016/065  
E102/B186

points of miscibility. The errors in measurement were not above 4%, for  $\text{He}^3$  concentrations up to 20% only; about 1%. The  $\alpha(T)$  curves were measured for 11.0, 33.0, 50.0, and 75.7%  $\text{He}^3$  between 1.5 and 4.2 °K; they lie lower, the higher the  $\text{He}^3$  content, between the curves for the pure components. The results are compared with the theory of I. Prigogine (Ann. Phys. (5), 1, 347, 1956). Agreement is found only for  $\text{He}^3$  concentrations up to about 10%. There are 4 figures.

TOPIC TAGS: electron paramagnetic resonance, cryogenic device, crystallography

ABSTRACT: A device is described and diagrammed which is designed to study electron paramagnetic resonance in the 8 mm wavelength range in crystals at low temperatures, down to  $0.314^{\circ}$  K. For the experiments, the sample under study is attached to a column in a millimeter band resonator, attached at two places to a thin-walled stainless steel tube 16 mm in diameter. The resonator is tuned by moving Melchior waveguides, a communicating diaphragm, and piston. The resonator, column, piston, and diaphragm are made of silvered brass. The lowest temperature is obtained by evacuation of vapor over liquid  $\text{He}^3$  with an adsorption pump. Orig. art. has: 1 figure. [JPRS]

TITLE: Equipment for investigating NMR at temperatures down to 0.3K

21,44,65  
SOURCE: Pribery i tekhnika eksperimenta, no. 3, 1965, 139-141

TOPIC TAGS: NMR, low temperature research, low temperature physics

ABSTRACT: The equipment for obtaining near-0.3K temperatures was described in PTE, 1962, no. 3, 198. A temperature of 1.2-15K is attained by exhausting liquid-He<sup>3</sup> vapor in a cryostat; the vapor condenses in a dewar vessel. The condensate is further evaporated, with the vapor adsorbed by a carbon pump, which brings the final temperature down to 0.315K for 4 hours or more. NMR can be measured on He<sup>3</sup> nuclei in liquid, gas, and solid specimens. The same outfit permits measuring NMR at 4.2-1.4K, 20.4-14K, and 77-63K. NMR is studied by a pulse method, with a 4-μsec 90° pulse and a receiver passband of 100-200 kc; the resonance frequency of F<sup>19</sup> nuclei is 13.5 Mc. "The authors wish to thank S. A. Shigimaga and Ye. I. Kirillov for their great help in building and mounting the equipment."

TITLE: Equipment for generating temperatures from 4.2 to 0.3°K

SOURCE: Pribory i tekhnika eksperimenta, no. 5, 1966, 245-248

TOPIC TAGS: cryogenic device, cryogenic liquid cooling, cryogenics, cryostat, liquid helium, evaporative cooling

ABSTRACT: Two versions of cryogenic devices with no moving parts for the generation of temperatures from 4.2 to 0.3°K using carbon adsorption pumps are described. Utilizing liquid He<sup>4</sup>, temperatures down to 0.87°K can be obtained; this value can be further reduced to 0.3°K with He<sup>3</sup>. Both versions of the pump consists of several concentric dewar containers. The outer dewar is filled with liquid nitrogen, the inner with liquid He<sup>4</sup>. Within the inner dewar is a thin-walled metal hemisphere filled with carbon and connected through a valve with a small dewar cylinder also filled with He<sup>4</sup>. The carbon is cooled to the liquid helium temperature and thus readily adsorbs helium vapor rising from the cylindrical dewar, which leads to the gradual lowering of the temperature in this container. This method cooled helium down to 0.9°K. To reach 0.3°K,

UDC: 621.59

Card 1/2

ACC NR. AP6034251

a two stage pump, similar to the one already described, is used. In this pump, the inner dewar is filled with  $\text{He}^3$ , as is a small container within the attached cylindrical dewar.  $\text{He}^4$  is introduced into a second small container in the same dewar. This container is also connected to the hemisphere filled with carbon. Due to adsorption of vapor from both containers, the temperature of  $\text{He}^3$  can be lowered to  $0.3^\circ\text{K}$ . TITLE: Supersonic flow past ellipsoids

SOURCE: AN SSSR. Izvestiya. Mekhanika i mashinostroyeniye, no. 4, 1964, 29-32

TOPIC TAGS: supersonic flow, shock wave, detached shock wave, flow past ellipsoid, bow shock wave, mixed flow

ABSTRACT: The supersonic flow past families of oblate ellipsoids of revolution with half-axis ratios  $t=0.49, 0.34, \text{ and } 0.19$  and the positions of the detached shock waves have been experimentally investigated at free-stream Mach numbers between  $2.0 \cdot 10^6$  and  $2.5 \cdot 10^6$ . Graphs of the pressure distribution  $c_p/c_{p0}$ , the tangential and normal force coefficients  $c_t$  and  $c_n$ , and the effect of oblateness on  $dc_n/d\alpha$  were plotted. The shapes and positions of the bow shock waves were analyzed from direct shadow photographs at zero angle of incidence and

Card 1/2

L 8401-65

TITLE: Pressure distribution over surfaces of ellipsoids

SOURCE: Moscow, Universitet. Vestnik. Seriya 1. Matematika, mekhanika, no. 4, 1964, 42-48

TOPIC TAGS: supersonic flow, pressure distribution, shock wave, ellipsoidal flow, sonic point

ABSTRACT: The results of an experimental investigation on supersonic flow past models of oblate ellipsoids in the range of Mach 1.48—3.02 and Reynolds numbers from 2.0 to  $2.5 \cdot 10^6$  are presented. The pressure distribution over the surfaces of ellipsoids and its space pattern at various angles of attack set by rotating the model around its axis were determined. The flow field between the body and shock front and the position of the sonic point depending on the ratio of ellipsoid half axes were considered. Comparison of the experimental results with theoretical calculations using the Newton formula and data obtained by others is presented in graphs. It is

Card 1/2

ACCESSION NR: AP4042057

shown that the elongation of the ellipsoid ( $t \rightarrow 1$ ) as well as the increase in velocity lead to a decrease in the subsonic region and draw the sonic point nearer to a critical point. Orig. art. has: 6 figures and 2 formulas.

TITLE: An investigation of pressure distribution on certain starlike bodies at nearly  
4 M

SOURCE: Zhurnal prikladnoy mekhaniki i tekhnicheskoy fiziki, no. 6, 1965, 122-125

TOPIC TAGS: aerodynamics, supersonic flow, shock tube, angle of attack, pressure distribution, wave drag, aerodynamic boundary layer, shock wave

ABSTRACT: The results of an experimental investigation of pressure distribution on star-like bodies (see Fig. 1) in supersonic flows in an aerodynamic wind tunnel at  $M = 3.85 \pm 0.1$  and  $Re = 6.0 \times 10^6$  are presented. The models, experimental setup, and measuring techniques are described in detail. Pressure measurements were obtained by manometers with tetrabromoethane liquid (density =  $2.96 \text{ g/cm}^3$ ). The boundary layer effect upon the flow structure for various angles between wings is investigated and shock wave structures for various angles of attack (from  $5$  to  $15^\circ$ ) are analyzed. A comparison of the experimental results with the exact theoretical data obtained previously by the author shows good agreement for all models. The ratios between the wave drags of equivalent circular cones and wave drags of models calculated from

TITLE: Separation of the turbulent boundary layer in a supersonic flow

SOURCE: Prikladnaya mekhanika, v. 2, no. 1, 1966, 99-105

TOPIC TAGS: supersonic flow, turbulent boundary layer, boundary layer separation

ABSTRACT: Experimental data on the interaction between shock waves and the turbulent layer in a supersonic flow is analyzed. A single relationship for determining the critical value of the shock intensity at which the separation of the boundary layer occurs, is obtained, in relation to the Mach number of the oncoming flow. The cases of an incident shock wave (see Fig. 1) and a supersonic flow around a vertical shoulder (Fig. 2) are considered; 1 - incident shock wave, 2 - shock causing separation of the boundary layer, 3 - stagnation zone, 4 - expansion-shock fan, 5 - reflected shock wave (boundary layer shown by dotted line);  $\delta$  is the boundary-layer thickness. The mechanisms of the flow separation in both cases are described, the effects of flow and shock parameters (density, velocity, Mach number, pressure gradient, viscosity)

TITLE: Investigation of flow past elliptic cones

SOURCE: AN SSSR. Izvestiya. Mekhanika zhidkosti i gaza, no. 1, 1966, 130-137

TOPIC TAGS: aerodynamics, transonic flow, supersonic flow, wind tunnel, conic flow, linear equation, shock wave structure

ABSTRACT: An experimental investigation of three-dimensional transonic and supersonic flows past elliptic cones in an aerodynamic wind tunnel is presented. Six models of elliptic cones with different eccentricities and half-cone angles  $\epsilon = 15^\circ, 22^\circ 30',$  and  $30^\circ$  were investigated at  $M = 0.58, 0.97, 1.19, 1.47, 3;$   $Re$  from  $1.2 \times 10^6$  at  $M = 0.58$  to  $3.0 \times 10^6$  at  $M = 3;$  angle of attack  $\alpha$  from  $0$  to  $15^\circ;$  angle of roll  $\phi$  from  $0$  to  $45^\circ$  and angle of yaw  $\beta = 0, 5, 10$  and  $15^\circ.$  The results are presented in graphs and compared with available theoretical and experimental data obtained by many authors. The comparisons show that the nonlinear thin-body theory agrees satisfactorily with experimental data for slender elliptic cones in a limited range of  $M;$  however, as may be seen from Fig. 1, the theoretical values lie substantially lower than the ex-

perimental values, in proportion to the increases in flow velocity and cone width. Various methods used for calculating supersonic and hypersonic flows around conic bodies are reviewed, analyzed, and at times compared. Comparisons of methods such as tangential and equivalent-cone with the improved equivalent-cone method of Willi F. Jacobs show that the results of the first two agree satisfactorily with experiment only for bodies which do not deviate substantially from circular cones, though those obtained by the third method agree much better with experimental data (dotted line, Model 1, Fig. 1). Optical investigations of all models at low M numbers showed that the shock fronts retain the same form of nearly circular cones and the local angle of the compression shock depends more on surface distribution along the body axis than on the shape of the body cross section. As the flow velocity increases, the shape of the shock wave in the section normal to the direction of flow approaches the shape of the body and the compression shock takes a conic, nonaxisymmetric form. Orig. art. has: 9 figures and 2 formulas. [AB]

TITLE: Three-dimensional flow past blunt-nosed cones

SOURCE: Moscow. Universitet. Vestnik. Seriya I. Matematika, mekhanika, no. 5, 1966, 85-89

TOPIC TAGS: supersonic aerodynamics, detached shock wave, shock wave structure, flow analysis, hypersonic flow, aerodynamic force, pressure distribution

ABSTRACT: Experimental results of a study of supersonic flows ( $M = 1.5$  to  $3$ ) past blunt nosed cones and the positions of detached shock waves are presented in graphs and compared with available experimental and theoretical data. The models were blunted cones with  $10^\circ$  semiapex angles with bluntness formed by ellipsoids of revolution with semiaxis ratios  $t = 0.2, 0.35$ , and  $0.5$ . Particular attention is devoted to the problem of pressure distribution over the surfaces of the cones and the position of the detached shock waves. The aerodynamic characteristics of various cones were determined from experimental data on pressure distribution by the approximate method developed by the author (Izvestia VUZ. Mekhanika i mashinostroyeniye, no. 4, 1964). The effects of the nose shape of flow configuration and on wave drag at angles of attack  $\alpha = 0, 5, 10, 15^\circ$  are presented in graphs and discussed. The

Card 1/2

analysis of the shock wave shape and the detachment distance from the body. Photographs show that the shape of the detached shock wave is nearly parabolic and approaches the body with increasing  $M$  and  $t$ . The shock wave shape in the initial part of conic surface is determined on the whole by the geometry of the elliptic part of the model. It is pointed out that the variation of the shock wave position due to the angle of attack is not large with respect to velocity coordinates system. Orig. art. has: 7 figures.

TOPIC TAGS: flow structure, boundary layer, model, angle of attack, stagnant zone, supersonic flow

ABSTRACT: To explain the flow structure, a visual representation was made of the surface streamlines near step, fastened to a flat sharp plate, with the M number of the advancing flow equal to 3.01. The boundary layer on the plate was turbulent. The surface of the model was coated with oil mixed with carbon black prior to the test. A diagram of the flow around the step is presented; equations are given describing the flow in this zone. Results are presented of studies of the supersonic flow around blunt bodies at  $M = 1.5$  to 3.0 at angles of attack ranging from 0 to 40 degrees. The tests results included spectra of the flow around

Card 1/2

ACC NR: AR6033805

models, the shape of the stagnant zone, as well as the dependence of the occurrence of separation on the lateral surface and the dependence of the coefficient of the bottom pressure on the M number of the advancing flow and the angle of attack. It was found that hysteresis takes place during the occurrence of separation on the lateral surface of the reverse cones. B. I. Bakun. [Translation of abstract]

SOURCE: Prikladnaya mekhanika, v. 2, no. 6, 1966, 108-111

TOPIC TAGS: supersonic aerodynamics, supersonic flow, base pressure, wind tunnel

ABSTRACT: The results of an experimental investigation of the base pressure near the trailing edge of axisymmetric models of small aspect ratio with nose-section bluntness of various shapes are reported. The experiments were carried out in order to establish and to clarify the dependence of the base pressure and other flow parameters near the trailing edge of models in supersonic flow, on the blunt shape of the forward section, in a supersonic wind tunnel with Mach numbers ranging from 1.5 to 3.5. Cylindrical models with removable elliptical and plane front sections were used. The experimental setup and the apparatus used are described briefly. The results are presented in graphs and seem to be in good agreement with theoretical data obtained

TITLE: Investigation of base pressure fluctuations behind a cone in supersonic flow

SOURCE: AN SSSR. Izvestiya. Mekhanika zhidkosti i gaza, no. 6, 1966, 129-134

TOPIC TAGS: supersonic aerodynamics, supersonic flow, base pressure, pressure gage, pressure measurement, pressure transducer, wake flow

ABSTRACT: A detailed description is presented of a highly accurate experimental investigation of the base pressure fluctuations behind a cone of semi apex angle of  $10^\circ$  with aft section diameters  $d = 100, 130$  and  $150$  mm in supersonic flow of  $M = 3$ . A specially designed pressure sensor was used for measuring base pressure fluctuations which uses the dependence of corona discharge parameters in a gas upon pressure. Its construction, operation and calibration are described in detail. The level of noise background of the experimental tube was measured in order to compare it with output signal of the pressure sensor, and the oscillations of the model were recorded by N-102 oscillograph with the aid of two strain gages fastened on model supports. Oscillographic recording of the base pressure fluctuation spectra are presented for the model with base of  $150$  mm in diameter at pressure of  $5$  atm, and show that the amplitude of fluctuations and frequency range increase with cone diameter. The same

pattern can be observed with increasing pressure in the mixing region. The amplitude maxima are obtained at frequencies higher than 100C, that is, they do not coincide with oscillation frequencies of the model (40—50 c). In order to throw more light on the behaviour of the flow in the base region, the flow structure behind the cone base was investigated with the aid of plates coated with a luminescent paint. The presence of an axisymmetric reverse flow coming from the wake throat to the cone base and a toroidal vortex flow occupying the region between reverse flow and dividing

Card 2/3

ACC NR: AP7001582

streamline (see Fig. 1) is discussed. The causes of high and low-frequency fluctuations of base pressure are analyzed and tentatively explained. Assumption is made that the total head in the reverse flow is proportional to the dynamic head of the outer flow in region 3 which ejects the gas from the stagnation region. The dynamic head in this region, in turn, is directly proportional to the pressure head of the free flow. Consequently the total energy and maximum amplitude of base pressure fluctuations should be proportional to the dynamic head of the free flow. It is said in the conclusion that the spectrum of the base pressure fluctuations represents a very complex superposition of a series of harmonic fluctuations. Orig. art. has: 7 figures. [AB]

The Development of Vertical Fractures in Hydraulic Fracturing

(Obrazovaniye vertikal'nykh treshchin pri gidrorazryve)

PERIODICAL: Neftyanoye khozyaystvo, 1958, Nr 10, pp 39-43 (USSR)

ABSTRACT: This is a continuation of an article published in "Neftyanoye khozyaystvo", 1958, Nr 9. The present article presents the results of 16 fracturing operations carried out under laboratory conditions (Table 1). The experiments showed that all the samples developed vertical fractures, that 54.1 percent of the cases developed two fractures (Table 2), that the vertical and radial fractures were shallow, and that the fractures developed in a vertical direction in spite of an attempt to orient them otherwise. The development of the fractures in a vertical direction is in contradiction with the view of many authors who maintain that fractures must develop along the lines of the rock strata. There are 2 tables and 2 Soviet references.
